

# ALGEBRAIC STRUCTURE OF CONVOLUTIONAL ENCODERS

Jorge *Pedraza-Arpasi*

## *Abstract*

*Traditionally the convolutional encoders were regarded as machines from automata theory without any algebraic structure.*

*In this work we give a group structure on such encoders and get some elemental results.*

**Introduction.** In direction to give an algebraic fundamentals of convolutional encoders, in a first step we observe that all known convolutional encoders, found in the respective literature, are over algebraic fields, i.e. its input alphabet, output alphabet, and state space are in a cartesian product of a field. After some manipulations we can see that this encoder uses only the first operation of the field, namely, the “sum”. Because this fact, our convolutional encoders will be over groups.

We define the *encoders* as *machines* in the sense of [6]. So, when we say the terms *encoder* or *machine*; we will be talking about the same thing. In the first section we take the inputs, outputs, and the states of the machine, strictly, over an abelian group, and we name this machine as Elementary Convolutional Encoder (ECE). The whole class of known encoders is included in this family of ECEs. We point out ECE's properties that will be a guide for the definition of generalized machines.

Like a collateral result, we give a technique to obtain a new machine from a given "old" machine. The characteristics of the new machine is that it has less states, the same inputs, and outputs than the old. We think by using the Axiom of the States, in the sense of [5]; this could be a practical way to find minimal encoders. A practical example is given.

In the second section, in order to define convolutional encoder machines over any group, abelian or not, we define the Schreier Product of groups. By using this product we define a General Convolutional Encoder (GCE). Of course, as is expected a ECE is a particular case of a GCE. Moreover, this class of GCEs is so wide that some restrictions are necessary. For instance, we introduce the controllability restriction. So, only, will it be considered controllable machines. Finally we give criteria to build non-trivial convolutional encoders and some examples.

## 1 Elementary Convolutional Encoder (ECE) and Reduction of States

Given  $k, n \in \mathbb{N}$ , consider a matrix  $T = (t_{ij}); 1 \leq i \leq k; 1 \leq j \leq n; t_{ij} \in \mathbb{Z} = \text{Integers Set}$ .

Let  $G$  be an abelian group. For any  $n \in \mathbb{N}$ , consider  $G^n$  the cartesian product of  $G$ . With the  $G$ -operation over the coordinates;  $G^n$  is, also abelian group.

Given  $x \in G^k$  and  $T$  as above, consider the product

$$x.T = \left( \sum_{i=1}^k x_i t_{i1}, \sum_{i=1}^k x_i t_{i2}, \dots, \sum_{i=1}^k x_i t_{in} \right);$$

where

$$x_i t_{ij} = \begin{cases} \overbrace{x_i * x_i \dots * x_i}^{t_{ij} \text{ - times}} & \text{if } t_{ij} > 0 \\ e_G & \text{if } t_{ij} = 0 \\ \underbrace{(x_i * x_i \dots * x_i)^{-1}}_{|t_{ij}| \text{ - times}} & \text{if } t_{ij} < 0 \end{cases}$$

Because the abelian condition of  $G$  and  $G^n$  we can write the plus symbol (+) instead the star (\*), and to denote 0 instead  $e_G$ . So, we are ready for ECE's definition.

**Def 1** Let  $n, k, m$  be natural numbers such that  $n > k \geq 1$ ;  $m \geq 1$ . Consider the matrices  $T^0, T^1, \dots, T^m$ ; with  $T^i = (t_{rs}^i); t_{rs}^i \in \mathbb{Z}; 1 \leq r \leq k; 1 \leq s \leq n; i = 0, 1, \dots, m$ .

We define an Elementary Convolutional Encoder (ECE); with parameters  $n, k, m$ ; over  $G$ ; as a machine  $M = (X, Y, Q, \delta, \beta)$ ; where:

$X \subset G^k$ ; is the, finite, set of input alphabets,

$Y \subset G^n$ ; is the set of output alphabets,

$Q = \{q = (x^1, x^2, \dots, x^m) / x^i \in X\} \subset (G^k)^m \approx G^{km}$ ;  
is the set (or space) of the machine states,

$\delta: X \times Q \rightarrow Q$ ; is defined by,  
 $\delta(x^0, q) = \delta(x^0, x^1, x^2, \dots, x^m) = (x^0, x^1, x^2, \dots, x^{m-1})$

$\beta: X \times Q \rightarrow Y$  is a surjective map, defined by  
 $\beta(x^0, q) = \beta(x^0, x^1, x^2, \dots, x^m) = x^0 T^0 + x^1 T^1 + x^2 T^2 + \dots + x^m T^m$ .

## 1.1 Some Properties of the ECE

**pp 1** If  $X$  group, then  $Y$  and  $Q$  are groups.

**pp 2** If  $X$  is group, then  $\delta$  and  $\beta$  are homomorphisms of groups, with  $\delta$  being surjective.

**pp 3** Assume that  $X$  is a group. Let  $Y_0 = \{\beta(x, e_Q)\}_{x \in X}$  be the outputs "from" the neutral state  $e_Q$ .

Then, we have  $Y_0$  is a normal subgroup of  $Y$  and  $\frac{Y}{Y_0} \approx Q$

**pp 4** Assume  $X$  is a group. Let  $Y_1 = \{\beta(x, q) \mid \delta(x, q) = e_Q\}$  be the outputs "to" neutral state.

Then, we have  $Y_1$  is a normal subgroup of  $Y$  and  $\frac{Y}{Y_1} \approx Q$ .

### Proof 1

Given  $y = \sum_{i=0}^m x^i T^i \in Y$  and  $y' = \sum_{i=0}^m x'^i T^i \in Y$ , we have  $y+y' = \sum_{i=0}^m (x^i + x'^i) T^i \in Y$ ; because  $X$  is a group.

Analogously, given  $q = (x^1, x^2, \dots, x^m)$  and  $q' = (x'^1, x'^2, \dots, x'^m)$ , we have  $q+q' = (x^1 + x'^1, x^2 + x'^2, \dots, x^m + x'^m) \in Q$ , because  $X$  is a group

### Proof 2

Now  $X$  and  $Q$  are groups, hence  $X \times Q$  is a group. Thus  $\delta$  is a map between two groups. Let  $(x, q)$  and  $(x', q')$  be two elements of  $X \times Q$ , with  $q = (x^1, x^2, \dots, x^m)$  and  $q' = (x'^1, x'^2, \dots, x'^m)$ ; then

$$\begin{aligned} \delta((x, q) + (x', q')) &= \delta(x + x', q + q') = (x + x', x^1 + x'^1 + x^{m-1}) \\ &= (x, x^1, \dots, x^{m-1}) + (x', x'^1, \dots, x'^{m-1}) = \delta(x, q) + \delta(x', q'); \end{aligned}$$

therefore,  $\delta$  is a homomorphism of groups.

By other side, given  $q = (x^1, x^2, \dots, x^m) \in Q$ , take the state  $q_0 = (x^2, x^3, \dots, x^{m+1}) \in Q$  and  $x^1 \in X$ ; then  $\delta(x^1, q_0) = q$ . So,  $\delta$  is surjective.

Analogously is straightforward to show that  $\beta$  is a homomorphism.

### Proof 3

Define the map  $\psi: Y \rightarrow Q$ , putting

$$\psi(\beta(x, q)) = q.$$

Then,

$$\psi(\beta(x,q) + \beta(x',q')) = \psi(\beta(x+x', q+q')) = q+q' = \psi(\beta(x,q)) + \psi(\beta(x',q')).$$

Thus  $\psi$  is a surjective homomorphism.

$$\text{Ker}(\psi) = \{\beta(x,q) \mid q = \psi(\beta(x,q)) = 0\} = Y_0.$$

By the fundamental theorem of the homomorphisms:

$$\frac{Y}{Y_0} \approx Q$$

### Proof 4

In analogous way to **Proof 3**, by defining the map  $\psi: Y \rightarrow Q$  as

$$\psi(\beta(x,q)) = \delta(x,q)$$

## 1.2 Reduction of States

**pp 5** Let  $Q' \subset Q$  be a normal subgroup of  $Q$ . We write

$$Y' = \{\beta(x,q) \in Y \mid q \in Q' \text{ and } \delta(x,q) \in Q'\};$$

then  $Y'$  is normal subgroup of  $Y$ .

### Proof

Define the map  $f: Y \rightarrow \frac{Q}{Q'} \times \frac{Q}{Q'}$  as being:

$$\psi(\beta(x,q)) = (q+Q', \delta(x,q) + Q')$$

then

$$\begin{aligned} \psi(\beta(x,q) + \beta(x',q)) &= \psi(\beta(x+x', q+q')) \\ &= ((q+q') + Q', \delta(x+x', q+q') + Q') \\ &= (q+Q', \delta(x,q) + Q') + (q'+Q', \delta(x',q') + Q') \\ &= \psi(\beta(x,q)) + \psi(\beta(x',q')) \end{aligned}$$

$\text{Ker}(\psi) = \{\beta(x,q) / \psi(\beta(x,q)) = (Q', Q')\} = \{\beta(x,q) \in Y / q \in Q'; \delta(x,q) \in Q'\} = Y'$ . Thus  $Y'$  is normal in  $Y$ .

Note that, the above map  $\psi$  can be not surjective.

**Def 2** Given a machine  $M = (X, Y, Q, \delta, \beta)$ ; let  $Y' \subset Y$  and  $Q' \subset Q$  be like above; such that;  $\delta(0, q) \in Q', \forall q \in Q'$ .

Then, we define a new machine  $M' = (X, \frac{Y}{Y'}, \frac{Q}{Q'}, \delta', \beta')$ , where:

$$\delta' : X \times \frac{Q}{Q'} \rightarrow \frac{Q}{Q'} \text{ is given by}$$

$$\delta'((x, q) + Q') = \delta(x, q) + Q'$$

$$\beta' : X \times \frac{Q}{Q'} \rightarrow \frac{Y}{Y'} \text{ is given by}$$

$$\beta'((x, q) + Y') = \beta(x, q) + Y' \text{ (parallel transition class)}$$

The maps  $\delta'$  and  $\beta'$ , are well defined; i.e.; they are independent of the representant of the class  $q + Q'$ . Thus the new machine  $M'$  is a well defined ECE. Therefore it have the properties 1.1. So,  $\delta'$  and  $\beta'$  are surjective homomorphisms; the sets

$$Y_{Q'0} = \{\beta'(x, Q'); x \in X\};$$

$$Y_{Q'1} = \{\beta'(x, q + Q'); (x, q + Q') \in X \times \frac{Q}{Q'} \text{ and } \delta'(x, q + Q') = Q'\};$$

are normal subgroups of  $\frac{Y}{Y'}$  and

$$\frac{Y_{Q'0}}{Y_{Q'1}} \approx \frac{Y}{Y'} \approx \frac{Q}{Q'}$$

### 1.3 A family of Reduced Machines

Given a Machine  $M = (X, Y, Q, \delta, \beta)$  with  $T^0$  as the **Def 1**, we consider the family of subsets of  $Q$  defined by

$$Q^i = \{q = (x^1, x^2, \dots, x^m) \in Q \text{ such that } x^1, x^2, \dots, x^i \in \text{Ker}(T^0)\};$$

$i=1, 2, \dots, m$

**pp 6**  $Q^i$  is a normal subgroup of  $Q$ ;  $\forall i=1, \dots, m$

#### Proof

Given  $q \in Q^i$ , we write  $q = (x, y)$ , with  $x = (x^1, x^2, \dots, x^i)$  and  $y = (x^{i+1}, \dots, x^m)$ . Also, we write

$$x * T^0 = x^1 T^0 + x^2 T^0 + \dots + x^i T^0;$$

we have, always,  $x * T^0 = 0$ .

Let  $(x, q)$  and  $(x', q')$  be elements of  $Q^i$ . Then

$$(x, q) + (x', q') = (x+x', y+y'),$$

and  $(x+x') * T^0 = 0$ . This jointly to the abelian condition of  $Q$  shows the normality of  $Q^i$ .

A characteristic of the family  $\{Q^i\}_{i=1}^m$ , is that

$$Q^m \subseteq Q^{m-1} \subseteq \dots \subseteq Q^1 \subseteq Q.$$

Hence, we will have

$$|Q| \geq | \frac{Q}{Q^m} | \geq \dots \geq | \frac{Q}{Q^1} |.$$

Now, let  $Y^i$  be a subset of  $Y$  defined by

$$Y^i = \{\beta(x, q) \in Y \mid q \in Q^i \text{ and } \delta(x, q) \in Q^i\};$$

by **pp 5**,  $Y^i$  is normal in  $Y$ ;  $\forall i = 1, 2, \dots, m$

**pp 7**  $\forall q \in Q^i$ , we have,  $\delta(0, q) \in Q^i$

**Proof**

Let  $q = (x^1, x^2, \dots, x^i, x^{i+1}, \dots, x^m)$  be a element of  $Q^i$

We have

$$\begin{aligned} \delta(0, q) &= \delta(0, (x^1, x^2, \dots, x^i, x^{i+1}, \dots, x^m)) \\ &= (0, x^1, x^2, \dots, x^{i-1}, x^i, x^{i+1}, \dots, x^{m-1}) \end{aligned}$$

Making  $x' = (0, x^1, x^2, \dots, x^{i-1})$  we have  $x' * T^0 = 0$ .

Therefore  $\delta(0, q) \in Q^i$

In this way, we can define a family  $\{M^i\}_{i=1}^m$ , of machines, putting for each machine:

$$M^i = (X, \frac{Y}{Y^i}, \frac{Q}{Q^i}, \delta_i, \beta_i);$$

with

$$\begin{aligned} \delta_i(x, q + Q^i) &= \delta(x, q) + Q^i \\ \beta_i(x, q + Q^i) &= \beta(x, q) + Y^i \end{aligned}$$

**1.4 Example**

Given  $G = Z_2$ ,  $n = 3$ ,  $k = 2$ ,  $m = 2$ ;  $T^0 = \begin{pmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \end{pmatrix}$   $T^1 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}$   $T^2 = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix}$ ; we have:

$$X = Z_2^2 = \{00, 01, 10, 11\}$$

$$Q = X^2 = Z_2^4 = \left\{ \begin{array}{l} 0000 \ 0100 \ 1000 \ 1100 \ 0001 \ 0101 \ 1001 \\ 0010 \ 0110 \ 1010 \ 1110 \ 0011 \ 0111 \ 1111 \end{array} \right\}$$

$$Y = Z_2^3 = \{000, 001, 010, 100, 011, 110, 101, 111\}$$

$$\delta(x^0, q) = \delta(x^0, (x^1, x^2)) = (x^0, x^1), x^i \in Z_2^2$$

$$\beta(x^0, q) = \beta(x^0, (x^1, x^2)) = x^0 T^0 + x^1 T^1 + x^2 T^2.$$

The trellis representation of  $M$ , is showed in the Figure 1.

Figure 1: Trellis diagram for the machine  $M$

### 1.4.1 Reduced Machine $M^2$

$$Q^2 = \{0000, 0011, 1100, 1111\} \Rightarrow \begin{cases} \text{classes} & \left\{ \begin{array}{l} 1000 + Q^2 = \{1000, 1011, 0100, 0111\} \\ 1001 + Q^2 = \{1001, 1010, 0101, 0110\} \\ 1101 + Q^2 = \{1101, 1110, 0001, 0010\} \end{array} \right. \end{cases}$$

$$Y^2 = \{000, 110\} \Rightarrow \begin{cases} \text{classes} & \left\{ \begin{array}{l} 100 + Y^2 = \{100, 010\} \\ 001 + Y^2 = \{001, 111\} \\ 011 + Y^2 = \{011, 101\} \end{array} \right. \end{cases}$$

$$\frac{Q}{Q^2} = \{Q^2, 1000 + Q^2, 0001 + Q^2\}$$

$$\frac{Y}{Y^2} = \{Y^2, 100 + Y^2, 001 + Y^2, 011 + Y^2\}$$

$$\delta_2(x, Q^2) = \begin{cases} Q^2, & \text{if } x \in \{00,11\} \\ 1000 + Q^2, & \text{if } x \in \{00,11\} \end{cases}$$

$$\delta_2(x, 1000 + Q^2) = \begin{cases} 1001 + Q^2, & \text{if } x \in \{00,11\} \\ 1000 + Q^2, & \text{if } x \in \{01,10\} \end{cases}$$

$$\delta_2(x, 1001 + Q^2) = \begin{cases} 1101 + Q^2, & \text{if } x \in \{00,11\} \\ 1001 + Q^2, & \text{if } x \in \{01,10\} \end{cases}$$

$$\delta_2(x, 1011 + Q^2) = \begin{cases} Q^2, & \text{if } x \in \{00,11\} \\ 1000 + Q^2, & \text{if } x \in \{01,10\} \end{cases}$$

$$\beta_2(x, Q^2) = \begin{cases} Y^2, & \text{if } x \in \{00,11\} \\ 011 + Y^2, & \text{if } x \in \{01,10\} \end{cases}$$

$$\beta_2(x, 1000 + Q^2) = \begin{cases} 100 + Y^2, & \text{if } x \in \{00,11\} \\ 011 + Y^2, & \text{if } x \in \{01,10\} \end{cases}$$

$$\beta_2(x, 1001 + Q^2) = \begin{cases} Y^2, & \text{if } x \in \{00,11\} \\ 001 + Y^2, & \text{if } x \in \{01,10\} \end{cases}$$

$$\beta_2(x, 1101 + Q^2) = \begin{cases} Y^2, & \text{if } x \in \{00,11\} \\ 011 + Y^2, & \text{if } x \in \{01,10\} \end{cases}$$

The Trellis representation of  $M^2$  is given in the Figure 2.

a: Classes Outputs

b: Classes Contain Outputs

Figure 2: Trellis diagram for the machine  $M^2$

### 1.4.2 The Reduced Machine $M^1$

$$Q^1 = \{0000, 0011, 1100, 1111, 0001, 0010, 1101, 1110\}$$

$$1000+Q^1 = \{1000, 1010, 1001, 1011, 0100, 0101, 0110, 0111\}$$

(the other class)

$$Y^1 = \{000, 100, 010, 110\}$$

$$001 + Y^1 = \{001, 101, 011, 111\}$$
 (the other class)

$$\frac{Q}{Q^1} = \{Q^1, 1001 + Q^1\}$$

$$\frac{Y}{Q^1} = \{Y^1, 001 + Y^2\}$$

$$\delta_1(x, Q^1) = \begin{cases} Q^1, & \text{if } x \in \{00,11\} \\ 1000 + Q^1, & \text{if } x \in \{01,10\} \end{cases}$$

$$\delta_2(x, 1000 + Q^1) = \begin{cases} Q^1, & \text{if } x \in \{00,11\} \\ 1000 + Q^1, & \text{if } x \in \{01,10\} \end{cases}$$

$$\beta_1(x, Q^1) = \begin{cases} Y^1, & \text{if } x \in \{00,11\} \\ 001 + Y^1, & \text{if } x \in \{01,10\} \end{cases}$$

$$\beta_2(x, 1000 + Q^1) = \begin{cases} Y^1, & \text{if } x \in \{00,11\} \\ 001 + Y^1, & \text{if } x \in \{01,10\} \end{cases}$$

The trellis representation of  $M^1$  is showed in the Figure 3.

## 2 General Convolutional Encoder (GCE)

### 2.1 Schreier Product

**Def 3** Let  $H$  and  $K$  be, two finite groups. Let  $\sigma: K \rightarrow \text{Aut}(H)$  and  $\mu: K \times K \rightarrow H$  be; mappings such that  $\forall k_1, k_2, k_3 \in K$  and  $\forall h \in H$ , satisfying the following two conditions:

$$\sigma(k_1) (\mu(k_2, k_3)) \cdot \mu(k_1, k_2, k_3) = (\mu(k_1, k_2)) \cdot \mu(k_1, k_2, k_3) \quad (1)$$

$$\sigma(k_1) (\sigma(k_2, h)) = \mu(k_1, k_2) \cdot \sigma(k_1, k_2) (h) \cdot \mu(k_1, k_2)^{-1} \quad (2)$$

We define the SCHREIER PRODUCT  $H_\sigma K$ , of  $H$  and  $K$  as the ordered pair group  $(h, k)$ , having the operation:

$$(h, k)^*(h', k') = (h \cdot \sigma(k)(h'), \mu(k, k'), kk').$$

So, the Schreier Product depends of the mappings  $\sigma$  and  $\mu$ .

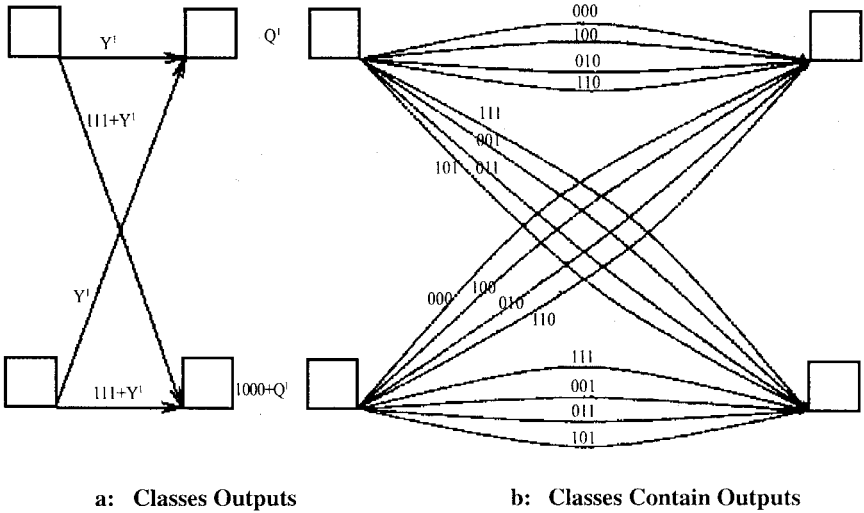

Figure 3: Trellis diagram for the machine  $M^1$

### 2.1.1 Some Properties

**pp 8** When  $\mu(k_1, k_2) = id, \forall k_1, k_2 \in K$ ; and  $\sigma$  is a group homomorphism, we have the particular case of Semidirect Product.

When  $\mu(k_1, k_2) = id, \forall k_1, k_2 \in K$ ; and  $\sigma(k) = id, \forall k \in K$ , we have the particular case of Direct Product.

**pp 9** The neutral element of this, new, group is  $(\mu(e_K, e_K)^{-1}, e_K)$ . And the inverse element of any  $(x, q)$  is

$$(x, q)^{-1} = (\sigma(q)^{-1} [\mu(q, q^{-1}) \cdot \mu(e_K, e_K) \cdot x]^{-1}, q^{-1})$$

**pp 10** If  $H \alpha K$  is a semidirect product, with  $\sigma \neq id$ , then is not abelian.

**pp 11** The mapping  $\varphi: H \rightarrow H \alpha K$  given by  $\varphi(h) = (\mu(e_K, e_K)^{-1} h, e_K)$  and the projection  $\pi_2: H \alpha K$  given by  $\pi_2(h, k) = k$  are group homomorphisms.

Conversily; if  $H \times K$  is a group such that the mappings  $\varphi$  y  $\pi_2$ , as above, are homomorphisms, then  $H \times K$  is a Schreier Product.

Because the **pp 8** is almost evident, and the **pp 9** and **pp 10** are indicate in [4], and the **pp 11** is implicitly showed in [2]; we omit the proof of these properties.

## 2.2 General Encoder Machine

**Def 4** Let  $X$ ,  $Q$  and  $Y$  be groups, with  $X$  and  $Q$  finites. Let  $X_\alpha Q$  be, a Schreier Product. Let  $\delta: X_\alpha Q \rightarrow Q$  and  $\beta: X_\alpha Q \rightarrow Y$  be group homomorphisms, with  $\delta$  surjective.

We define the General Convolution Encoder (GCE) as a machine  $M = (X, Y, Q, X_\alpha Q, \delta, \beta)$  such that the map  $\Psi: X_\alpha Q \rightarrow Q \times Y \times Q$ , given by  $\Psi(x, q) = (q, \beta(x, q), \delta(x, q))$  is injective.

### 2.2.1 Some Properties

**pp 12** The ECE is particular case of GCE

**pp 13** Let  $T = \text{Im}(\Psi) = \Psi(X_\alpha Q) \subset Q \times Y \times Q$ . Then  $T$  is a group and  $X_\alpha Q \approx T$ ; moreover

$$T_0 = \{(e_Q, \beta(x, e_Q), \delta(x, e_Q)) \in T \mid x \in X\},$$

and

$$T_1 = \{(q, \beta(x, q), \delta(x, q)) \in T \mid (x, q) \in X_\alpha Q, \delta(x, q) = e_Q\},$$

are normal subgroups of  $T$  and  $\frac{T}{T_0} \approx \frac{T}{T_1} \approx Q$ .

**pp 14** Given  $q \in Q$ , let

$$T_{q0} = \{(q, \beta(x, q), \delta(x, q)) \mid x \in X\}$$

be the transitions “from” the  $q$  state; and let

$$T_{q1} = \{(q', \beta(x, q'), \delta(x, q')) \in X_\alpha Q; \delta(x, q') = q\}$$

be the transitions “to” the  $q$  state.

Then  $T_{q0}$  is a lateral class for  $T_0$  and  $T_{q1}$  is a lateral class for  $T_1$

**Proof 12**

On the ECE, making the direct product  $X \times Q$  as a Schreier Product  $X_\alpha Q$ ; we see that the mapping  $\Psi$  of the **Def 4** is injective

**Proof 13**

Consider the group  $T = Q \times \beta(X_\alpha Q) \times Q \subseteq Q \times Y \times Q$ . The mapping  $\Psi$  is a homomorphism between  $X_\alpha Q$  and  $T$ . by the injectivity,  $X_\alpha Q \approx T$ .

By other side, considering the projection  $\pi_1 : T \rightarrow Q$ , given by

$$\pi_1(q, \beta(x, q), \delta(x, q)) = q;$$

we see that  $\pi_1$  is a surjective homomorphism with  $\text{Ker}(\pi_1) = T_0$ . Thus

$$\frac{T}{T_0} \approx Q.$$

Analogously, for  $T_1$

**Proof 14**

Given  $t'_q = (q, \beta(x', q), \delta(x', q))$ ;  $t_q = (q, \beta(x, q), \delta(x, q)) \in T_{q0}$ ; is suffice to show that  $t'_q t^{-1}_q \in T_0$ .

Indeed,

$$\begin{aligned} t'_q t^{-1}_q &= (q, \beta(x', q), \delta(x', q)); (q, \beta(x, q), \delta(x, q))^{-1} \\ &= (q, \beta(x', q), \delta(x', q)); (q^{-1}, \beta((x, q)^{-1}), \delta((x, q)^{-1})). \end{aligned}$$

But

$$(x, q)^{-1} = (\sigma(q)^{-1} [\mu(q, q^{-1}) \cdot \mu(e_k, e_k) \cdot x]^{-1}, q^{-1})$$

Hence, we can take  $(x, q)^{-1} = (x'', q^{-1})$ . Therefore

$$\begin{aligned} t'_q t^{-1}_q &= (e_Q, \beta((x', q)(x'', q^{-1})), \delta(x', q)(x'', q^{-1})) \\ &= (e_Q, \beta(x' \cdot \sigma(q)(x''), \mu(q, q^{-1}), e_Q), \delta(x' \cdot \sigma(q)(x''), \mu(q, q^{-1}), e_Q)) \in T_0 \end{aligned}$$

The proof for  $T_{q1}$  is similar

## 2.3 Some Criteria to Construct Encoders

**Def 5** Given an encoder  $M = (X, Y, Q, X_\alpha Q, \delta, \beta)$  we say that  $M$  is **controllable**, when  $\forall q, q' \in Q$ , there is a finite sequence  $\{x_1, x_2, \dots, x_n\} \subset X$ , such that

$$q' = \delta(x_n, \delta(x_{n-1}, \delta(x_{n-2}, \dots, \delta(x_2, \delta(x_1, q)) \dots))).$$

Our definition of controllability of encoders is compatible with the controllability of Codes given in [2], the controllability of Group Codes given in [3] and [1], and the controllability of Dynamical Systems given in [5] and [1].

**pp 15** Assume that the group  $Q$  is not trivial. If  $T_0$  and  $T_1$ , defined in **pp 13**, are equals; then the machine is non-controllable.

### Proof

Given any sequence  $\{x_i\}_{i=1}^n$ , we have

$$\delta(x_n, \delta(x_{n-1}, \delta(x_{n-2}, \delta(x_2, \delta(x_1, e_Q)) \dots))) = e_Q;$$

because,  $T_0 = T_1 = \{(e_Q, \beta(x, e_Q), e_Q) \mid x \in X\}$ .

Therefore for  $q \neq e_Q$ , there is not  $\{x_i\}_{i=1}^n$ , such that

$$q = \delta(x_n, \delta(x_{n-1}, \delta(x_{n-2}, \dots, \delta(x_2, \delta(x_1, e_Q)) \dots)))$$

By joining this result to fact  $X_\alpha Q \approx T$ ; we conclude that to build controllable machines is suffice to check the normal subgroups of  $X_\alpha Q$  such that they have the same cardinality than  $X$ . Therefore:

**pp 16** If the class:

$$\mathcal{X} = \{H \subset X_\alpha Q \text{ such that } H \text{ is a normal subgroup with } |H| = |X|\}$$

has not more than one element; then, the machine is non-controllable.

### 2.3.1 Examples

#### Ex 1

Let  $X = Z_4$  and  $Q = Z_5$  be two cyclic groups. The direct product  $Z_4 \times Z_5$  it have only one normal subgroup of cardinality four and only one of cardinality five. Therefore; there is not any controlable machine for this Schreier Product.

#### Ex 2

Let  $X = Q$  be the cyclic group

$$Z_4 = \{e_X = q_Q = e, \eta, \eta^2, \eta^3\}.$$

Let  $\sigma: Z_4 \rightarrow \text{Aut}(Z_4)$  be, the homomorphism defined by:

$$\sigma(\eta^i)(\eta^j) = \eta^{j \cdot 3^i}$$

Take the Schreier Product  $X_\alpha Q$  as being the Semidirect Product  $X_\sigma Q$  as being the Semidirect Product  $X_\alpha Q$ , with the operation

$$(x, q)(x', q') = (x \cdot \sigma(q)(x'), qq')$$

Since  $x = \eta^i, q = \eta^j, x' = \eta^r, q' = \eta^s$ , we have

$$\begin{aligned} (x, q)(x', q') &= (\eta^i, \eta^j)(\eta^r \cdot \sigma(\eta^j)(\eta^r), \eta^j \cdot \eta^s) \\ &= (\eta^{r \cdot 3^j + i}, \eta^{j+s}) \end{aligned}$$

In this way we can write;

$$X_\alpha Q = \left\{ \begin{array}{l} (0,0), (1,0), (2,0), (3,0), (0,1), (0,2), (0,3), (1,1), \\ (1,2), (1,3), (2,1), (3,1), (2,2), (3,2), (2,3), (3,3) \end{array} \right\}$$

And the operation over  $X_\sigma Q$  induced by  $\sigma$ , now is:

$$(i, j)(r, s) = (r3^j + i, j + s); (\text{Mod}4)$$

Also, we back to write

$$Z_4 = X = Q = \{0,1,2,3\}.$$

The normal subgroups of cardinality four are  $U_0 = \{(0,0), (1,0), (2,0), (3,0)\}$  and  $U_1 = \{(0,0), (1,2), (2,0), (3,2)\}$ .

For the definition of  $\delta$  in a way that it be a surjective homomorphism, we use the **pp 14**. We must take  $T_0 \approx U_0$  and  $T_1 \approx U_1$ . Therefore, if  $\delta: X_\sigma Q \rightarrow Q$  is defined, using the lateral classes of  $U_1$ , as being:

$$\delta(i,j) = \begin{cases} 0, & \text{if } (i,j) \in \{(0,0),(1,2),(2,0),(3,2)\} \\ 1, & \text{if } (i,j) \in \{(1,0) * (0,0),(1,2),(2,0),(3,2)\} \\ 2, & \text{if } (i,j) \in \{(0,1) * (0,0),(1,2),(2,0),(3,2)\} \\ 3, & \text{if } (i,j) \in \{(0,3) * (0,0),(1,2),(2,0),(3,2)\} \end{cases}$$

We have that  $\delta$  is a surjective homomorphism.

Finally by making  $Y = X_\sigma Q$ , we can define  $\beta=id$ . so, we have the machine  $M = (X,Y,Q, X_\sigma Q, \delta, \beta)$  whose trellis graphic is showed in the Figure 4.

**Figure 4:** Trellis diagram for the machine  $M = (X,Y,Q, X_\sigma Q, \delta, \beta)$
